

SUBSTITUTE ABSTRACT

Positioning screws provided with an attachment elements are set into the lingual-oral or palatal area and/or into the alveolar process of the jaw. Then an impression of the set positioning screws and adjacent areas of the jaw is taken and is fitted with positioning screws corresponding to the positioning screws in the jaw. The impression is used to make a drilling or transfer template for the implants to be installed, which is then fitted to the positioning screws in the jaw and used to drill implant holes and set implants or just to set implants. The template and the positioning screws are then removed from the jaw and after healing of the jaw and osseointegration of the implants, a dental prosthesis is fitted to the implants.
